Disability Identity-The Background

- Disability identity composed of personal and community dimensions.
- Personal identity = a person views themselves as a person with a disability
- Communal attachment = a person views themselves as connected to people with disabilities.
- Positive disability identity = higher satisfaction with life and well-being.
Objectives

• To explore the relationship between disability identity and well-being.

• To develop applied implications regarding disability identity awareness and development for both athletes and practitioners.
Methodology

- Cross-sectional design
- 58 elite para athletes, 28 males and 30 females
- 43 elite para athletes are Paralympians, representing 16 sports
- Quantitative measures:
  - Eight item Disability Personal Identity Scale
  - Six item psychological health sub-scale, WHO Quality of Life Instrument
Important Identities listed (M=5.55; SD3.12) around 10 themes, 19 athletes listed personality traits rather than roles or groups.

Acceptance of disability is aligned with better well-being, whilst denial of disability is linked with poorer well-being.
Implications

• Elite para athletes to become more accepting of themselves.
• Elite para athletes need to understand their broader self
  identity (EIS#moretome campaign)
• Social Identity Mapping (SIM) for athletes and practitioners
